

ProofNest — Firebase & Cloudinary Setup

Dashboard-only guide (no local CLI). Firebase project: **testproject-a9929**

Part 1 — Get Cloudinary credentials

1. Open <https://console.cloudinary.com> and sign in.
2. On the Dashboard home, note your **Cloud name** (e.g. dspdmxdaq), **API Key**, and **API Secret** (click Reveal). Keep the secret private.

Firebase env variable	Value
CLOUDINARY_CLOUD_NAME	e.g. dspdmxdaq
CLOUDINARY_API_KEY	From Cloudinary dashboard
CLOUDINARY_API_SECRET	From Cloudinary dashboard (secret)

Part 2 — Upgrade Firebase to Blaze

1. Open Firebase Console → project **testproject-a9929**.
2. Bottom left: Upgrade → choose **Blaze (pay as you go)**. Cloud Functions and outbound networking require Blaze.

Part 3 — Set Cloudinary environment variables

Your functions use **process.env** (Functions v2). Do **not** use the old *firebase functions:config:set* command.

Option A — Firebase Console (per function)

- Go to Firebase → Build → Functions (project testproject-a9929).
- After functions are deployed, open each function: **getCloudinaryUploadParams** and **sendNotification**.
- Open Configuration / Environment variables.
- Add CLOUDINARY_CLOUD_NAME, CLOUDINARY_API_KEY, CLOUDINARY_API_SECRET.
- Save and wait for the new revision to deploy.

Option B — Google Cloud Console

- Open Cloud Functions list for project testproject-a9929.
- Edit getCloudinaryUploadParams → Runtime environment variables → add the three vars → Deploy.
- Only getCloudinaryUploadParams strictly needs Cloudinary vars.

Optional — Secret Manager (safer for API secret)

- Google Cloud → Security → Secret Manager → Create secret CLOUDINARY_API_SECRET.
- In the function edit screen → Secrets → mount as env var CLOUDINARY_API_SECRET.

Part 4 — Deploy Firestore rules

1. Firebase Console → Firestore → Rules (project testproject-a9929).
2. In your repo, open **firestore.rules** (project root), copy all contents.
3. Paste into the Firebase Rules editor, replacing existing rules.
4. Click **Publish**.

Part 5 — Deploy Storage rules

1. Firebase Console → Storage → Rules (project testproject-a9929).
2. If Storage is not enabled: Get started → pick a region.
3. Open repo file **storage.rules**, copy all contents into the editor.
4. Click **Publish**.

Part 6 — Deploy Cloud Functions (browser Cloud Shell)

Firebase Console cannot upload **firebase/functions/index.js** by clicking alone. Use **Cloud Shell** in the browser (no local install).

- Firebase Console → project testproject-a9929 → Cloud Shell icon (top right).
- Clone or upload your project into Cloud Shell.
- Run: `npm install --prefix firebase/functions`
- Run: `npx firebase-tools login`
- Run: `npx firebase-tools use testproject-a9929`
- Run: `npx firebase-tools deploy --only functions`
- Confirm `getCloudinaryUploadParams`, `sendNotification`, `onNotificationCreated` appear under Functions.
- Re-apply env vars (Part 3) on the deployed revision if you set them before first deploy.

Cloud Shell commands (copy as a block):

```
npm install --prefix firebase/functions
npx firebase-tools login
npx firebase-tools use testproject-a9929
npx firebase-tools deploy --only functions
```

Part 7 — Verify in the app

1. Rebuild and install the Android app.
2. Sign in, complete inspection, open Review & Sign, draw signature, tap Confirm signature.

3. Should succeed without error_notfound.

4. Optional: upload a checklist photo or profile photo to test Cloudinary signed uploads.

Quick checklist

Step	Where	Done
Cloudinary credentials	console.cloudinary.com	■
Blaze plan	Firebase → Upgrade	■
CLOUDINARY_* env vars	Firebase / Cloud Functions → Edit	■
firestore.rules	Firebase → Firestore → Rules → Publish	■
storage.rules	Firebase → Storage → Rules → Publish	■
Function code deploy	Cloud Shell → <code>firebase deploy --only functions</code>	■

What NOT to use

- `firebase functions:config:set` — Gen 1 only; your code uses `process.env.CLOUDINARY_*`.
- Putting API secret in the Android app or `google-services.json` — server only.
